MKT, DIVISION OF KOEHRING CO. STANDARD WARRANTY

#### Abstract

"Koehring Company warrants new Products sold by it to be free from defects in material or workmanship for a period of 90 days after date of delivery to the first user and subject to the following conditions: "Koehring Company's obligation and liability under this Warranty is expressly limited to repairing or replacing at Koehring Company's option, any parts which appear to Koehring Company upon inspection to have been defective in material or workmanship. Such parts shall be provided at no cost to the user, at the business establishment of the authorized Koehring Company distributor of the Product during regular working hours. This Warranty shall not apply to component parts or accessories of Products not manufactured by Koehring Company and which carry the warranty of the manufacturer thereof, or to normal maintenance (such as engine tune-up) or to normal maintenance parts (such as oil filters). Replacement or repair parts installed in the Product covered by this Warranty are warranted only for the remainder of this Warranty as if such parts were original components of said Product. KOEHRING COMPANY MAKES NO OTHER WARRANTY, EXPRESS OR IMPLIED, AND MAKES NO WARRANTY OF MERCHANTABILITY OF FITNESS FOR ANY PARTICULAR PURPOSE. "Koehring Company's obligation under this Warranty shall not include any transportation charges, costs of installation, duty, taxes or any other charges whatsoever, or any liability for direct, indirect, incidental, or consequential damage or delay. If requested by Koehring Company, Products or parts for which a warranty claim is made are to be returned transportation prepaid to the Koehring Company division from which Product was originally shipped. Any improper use, including operation after discovery of defective or worn parts, operation beyond rated capacity, substitution of parts not approved by Koehring Company, or any alteration or repair by others in such manner as in Koehring Company's judgment affects the Product materially and adversely, shall void this Warranty. "NO EMPLOYEE OR REPRESENTATIVE IS AUTHORIZED TO CHANGE THIS WARRANTY IN ANY WAY OR GRANT ANY OTHER WARRANTY UNLESS SUCH CHANGE IS MADE IN WRITING AND SIGNED BY AN OFFICER OF KOEHRING COMPANY AT ITS HOME OFFICE."

Koehring
MKT Division
Dover, New Jersey 07801

This manual contains parts, descriptive maintenance, operational principles and trouble-shooting instructions for the McKiernan-Terry Model V-5 Vibratory Pile Driver/Extractor with Model HP-105 Hydraulic Power Pack.

Sufficient descriptive material, together with numerous photographs, schematics and line drawings are included to enable the operator to understand the basic construction of the vibrator and how the principles by which the hydraulic system functions.

## I. GENERAL DESCRIPTION

A. V-5 VIBRATOR

The V-5 Vibrator consists of four equal sized eccentrics powered by a single hydraulic gear motor. The hydraulic motor drives a jack shaft which in turn drives the four eccentrics through equal teeth gears. The vertical dynamic forces of the four eccentrics are additive causing a downward and upward movement. All horizontal dynamic forces are cancelled. These vibratory dynamic forces are transmitted to a pile section through clamping jaws that are hydraulically powered. The suspension assembly consists of springs that permit lifting or pile extracting.

The four eccentrics are stacked in a vertical column and mounted in heavy duty spherical roller bearings. One eccentric is directly coupled to a lubricating gear pump. The lube oil is forced to two upper discharge pipes that each guide oil into the upper two bearings and upper gear, splashing oil throughout the enclosure. The operating frequency of the $V-5$ is about 1350 cpm varying slightly lower by increasing load and slightly by engine speed droop. The amplitude depends on the total mass being vibrated and the resistance of the soil. The free hanging vibrator will have a total amplitude of $7 / 16-1 / 2$ inches. The hydraulic clamp is actuated by an $8^{\prime \prime}$ hydraulic cylinder with a $11 / 2$ inch maximum trave 1 developing about 31 tons at 2500 psi. There are two jaws, one fixed, and one movable in a side rocking motion to compensate for minor deformations in pile sections. Clamping or unclamping is accomplished in a second or less.

## I. GENERAL DESCRIPTION - Continued

## A. V-5 VIBRATOR - Continued

A pre-loaded, spring suspension system effectively isolates vibrations from the crane boom while vibrating on a pile. Free hanging, there may be some vibration transmitted to the lifting head when starting and stopping. The suspension assembly is designed for a maximum of 15 ton line pull when extracting. The lifting head has been made massive for maximum driving weight. Additional weights are not recommended. The large spring enclosures are designed for personnel safety. Operation of the vibrator without the spring enclosures is not recommended.

The V-5 Vibrator can operate underwater. However, the factory should be consulted for preparations and expected problems of corrosion.

The outer race of the eccentric bearings is a tight fit in the housings and a slip fit on the eccentric shafts. The center drive shaft bearing is a slip fit in the housing and a tight fit on the drive shaft (sometimes referred to as the jack shaft).

FIG. 3
I. GENERAL DESCRIPTION - Continued
B. HP-105 HYDRAULIC POWER PACK

A portable hydraulic power pack, designated HP-105, is used to develop the hydraulic energy to rotate the V-5 Vibrator eccentrics and open and close the clamp jaws. The skid mounted power package has reservoirs for hydraulic fluid and diesel fuel, is powered by a diesel engine and is complete with all necessary valving and gauges for the operation of the open loop drive and clamp circuits. The standard hydraulic power package is operated by manual valves located on top of the 80 Gal . reservoir. A single pump powers the vibrator clamp cylinder and the eccentric drive motor.

The two manual control valves are open center and not required to hold a load in neutral. One valve located on left will power the vibrator clamp cylinder. Clamp pressure will be maintained in the cylinder by a built-in check on the cylinder after the clamp valve is spring positioned to neutral. The other valve will direct flow from the pump to the vibrator eccentric motor requiring valve spool movement from detent positions.

FIG. 4
I. GENERAL DESCRIPTION - Continued
B. HP-105 HYDRAULIC POWER PACK - Continued

There is a built-in relief valve located in the input valve end. This relief valve controls the maximum pressure of $2,500 \mathrm{psi}$ for the clamp cylinder and for the eccentric motor, on the vibrator.

In the open loop circuit of the clamp cylinder and hydraulic motor, all return-to-tank oil is directed through the heat exchanger, located in front of the engine radiator and through a 25 micro-in-tank filter. The drive circuit powers the vibrator by supplying hydraulic oil under pressure through hoses which are connected to the power unit and to the hydraulic motor in the vibrator.

The hydraulic in-tank return line filter, located on top of the power pack has a full size by-pass valve that protects the filter element and system with a minimum of pressure loss. Ref. Fig. 6 below for cutaway of filter.

II. OPERATING INSTRUCTIONS
A. CONNECTION OF HOSES

All V-5 Vibrators are thoroughly tested at the factory and consequently all hose lines will be filled with hydraulic fluid. Generally, the hose bundle assembly filled with oil, is disconnected from the hydraulic power pack and the vibrator for shipment. Therefore, it is necessary, when reconnecting, to make the correct hose connections to the vibrator and power pack. There are five hoses in the bundle, each 100 ft . long. Two $11 / 4$ I.D. lines for the hydraulic motor, two $3 / 4$ I.D. lines for the hydraulic clamp cylinder and one $3 / 4$ I.D. line for the hydraulic motor case drain. Hose connections at the hydraulic power pack are made easily by quick disconnects with double checks. At the vibrator, it is important to connect the correct hoses which are originally color coded.

Refer to Fig. 7, for repair of hoses with re-usable fittings. When the hoses are attached to the boring unit, care should be made to have the bundle hang free. Extreme care should be made at all times not to kink any of the hoses.

To assemble
Step 1. Cut hose to length required. Hose must be stripped of its rubber cover before inserting in socket. Locate stripping point by putting hose end next to high pressure fitting as shown-from hose end of socket to noteh on socket.
Step 1A. Strip hose. Cut rubber cover around down to wire reinforcement. Slit lengthwise. Raise flap and pull off with pliers. Clean excess rubber off wirn re. inforcement with wire brush or soft wire wheel. Do not fray or flare wire reinforcement when brushing.

Step 2. Put socket in vise and screw hose into socket counter-clockwise until it bottoms.

Step 3, Oil nipple threads and inside of hose liberally. No assembly mandrel is needed for deuble wire braid and sparal wrap hose. Use grease instead of oil for larger suzes.

Step 4. Screw nipple clockwise into socket and hose. Leave $1 / m^{*}$ to $1 / s^{*}$ clesrance for takeup.

FIG. 7

## II. OPERATING INSTRUCTIONS

A. CONNECTION OF HOSES - Continued

Care should be taken to have all connections free from contamination especially the high pressure hydraulic motor lines. All hydraulic line connectors and quick disconnects, when disconnected, should be capped or plugged immediately to assure against contamination.

FIG. 8

FIG. 9

When the hoses are attached to the Vibrator, care should be made to have the bundle hang free and the larger hoses evenly supporting the load. Extreme care should be made at all times not to kink any of the hoses. As an example, the $11 / 4^{\prime \prime}$ I.D., $2^{\prime \prime} 0$. . hose has a minimum bending radius of 18 inches. Even though these hoses have a minimum bursting pressure of 12,000 psi, a kink will weaken the hose multiple spiral wire wrap reinforcement and rupture will result at high operating pressures.

The hose lines between the vibrator and the hydraulic power pack are 100 ft . long, made up of 50 ft . lengths. A damaged hose section of 50 ft . can be replaced or a repair connector inserted in the 3/4 I.D., $11 / 4$ O.D. hydraulic clamp lines and drain line (Refer to Fig. 7, Page 11). The $11 / 4$ I.D., 2 O.D. motor lines cannot be repaired in the field without special tooling.
II. OPERATING INSTRUCTIONS - Continued

## B. START AND WARM-UP ENGINE

Before starting the engine, read the engine manufacturer's operating and maintenance instructions carefully. Follow the engine starting operating and maintenance procedures detailed in the manual. CAUTION: DO NOT PUSH THROTTLE HANDLE TOO HARD FOR MAXIMUM SPEED OR CONTROL BRACKET WILL BEND.
C. FILLING THE HYDRAULIC LINES

Initially, motor hose lines and clamp lines, should be connected to the power unit and the other ends connected together, not to the vibrator. Running the engine initially at low speed with vibrate valve engaged to fill the lines, then full speed to rush maximum oil flow through the lines. After the vibrator has been connected to the hose lines, it is recommended that the engine speed is set low ( 1000 RPM) with the vibrator valve engaged. With the clamp lines attached to the vibrator, it will be necessary to bleed the lines at the cylinder always at the high pressure side of the cylinder. It will be necessary to run the engine at full speed when bleeding the clamp cylinder with clamp valve engaged because full flow will be over relief.

FIG. 10
II. OPERATING INSTRUCTIONS - Continued
D. OPERATING VALVES

Different valve assemblies are used on the HP-105 Power Packs. The first of two valve levers, one on the left, operates the clamp jaws. Moving the lever one direction inward or push opens the jaws and the other direction, pull, closes the jaws. The valve handle is spring loaded and must be held to operate or it will spring back to neutral position. The clamp cylinder will operate very quickly or equivalent to about $1 / 2 \mathrm{sec}$. at pump flows of about 50 GPM. Clamp pressure with jaws closed will be held by the check valve on the cylinder. The clamp handle must be in the neutral position before pulling the vibrate valve handle. The vibrate valve handle, one on the right is not spring loaded and can be pulled to vibrate and left in that position. Only one direction is required on the vibrate valve handle because the vibrator is to run in one direction as is the lube pump. The lube pump is powered by one of the eccentric shafts and is unidirectional pumping. The relief valve is located on the valve. The pressure gage on the manual valve is used to view pressure of both the clamp circuit and vibrate circuit. While the vibrate valve handle is pulled to power the vibrator, the clamp handle is not to be pulled or pushed or all oil will be directed from the vibrator to the clamp circuit. Ref. Hydraulic Schematic, Fig. 21, Page 31.

## II. OPERATING INSTRUCTIONS

## E. CHARACTERISTICS

The varying characteristics of the V-5 Vibrator can be seen on the frequency vs. dynamic force graph, Fig. 15, Page 20. The four eccentrics in the vibrator are fixed in size and the resulting dynamic force of the vibrator is directly proportionate to the square of the angular frequency. As an example, at 1400 CPM vibrator frequency, the theoretical vertical dynamic force is about $55,000 \mathrm{lbs}$. The power of the vibrator is generally referred to the hydraulic motor output power and is dependent on hydraulic flow and pressure. Fig. 15 has the horsepower curves as a function of pressure and frequency or the hydraulic flow converted to hydraulic motor speed. For a given hydraulic motor speed, which is vibrator frequency since the motor is driving the eccentrics directly, as an example 1400 RPM, the motor output horsepower is about 44 at 2000 psi fluid pressure.

The clamp lever on the valve need only be pushed or pulled and held for a second or more to open or close the jaws respectively. As can be seen on the Hydraulic Schematic, Fig. 21, Page 30, there is equal oil pressure on both sides of the clamp cylinder when the clamp handle is in the neutral position. Oil pressure in the neutral position, with flow directly to tank, is a result of restrictions of maximum flow going through the oil cooler, the filter and long piping lines. This neutral position pressure is about $200-250$ psi. Equal pressure on both sides of the cylinder piston could cause the piston to extend or cause the jaws to close when in the "open" position. However, a stiff spring on the free flow of the cylinder check, Fig. 10, Page 13 is adequate to restrict piston movement.

## II. OPERATING INSTRUCTIONS

## E. CHARACTERISTICS - Continued

The hydraulic gear pump used on the HP-105 Hydraulic Power unit and the hydraulic gear motor used on the V-5 Vibrator have varying output characteristics dependent on speed or flow and pressure. Reference the performance characteristics of the Tyrone Hydraulic Pump 20300, Fig. 13, Page 17, and the Tyrone Hydraulic Motor 20350, Fig. 14, Page 18. For reference to engine speed, refer to the engine tachometer as shown on Fig. 12 below.

FIG. 12

FIG. 13

- 17 -

FIG. 14

## II. OPERATING INSTRUCTIONS

## E. CHARACTERISTICS - Continued

The varying vibrator frequency with changing loads is a characteristic of a hydraulic gear pump and hydraulic gear motor. The changing frequency of the vibrator will not be obvious unless a frequency meter check is made. A minimum frequency of about 1000 CPM is recommended under maximum load to assure that the suspension springs are not excited at or near their natural frequency. Below 1000 cpm , the lifting head may bounce or go through a larger amplitude than the excitation amplitude of the exciter assembly.

The hydraulic power pack engine speed determines pump flow. The maximum recommended engine speed set at the factory is 2200 RPM at no load. The maximum operating pressure recommended is 2500 psi, generally set with the vibrator operating on a pile at maximum load. The maximum engine droop should be from 2200 RPM to 2000 . As the vibrator resistance is increased, calling for higher pressure, hydraulic oil will pass over relief causing the vibrator to slow down. If the frequency drops below 1000 CPM, the vibrator is over-loaded and its driving capabilities will greatly reduce. Reference the dynamic force of the vibrator at varying frequencies on Fig. 15, Page 20. A secondary characteristic of a very low operating frequency, say 600-900 CPM, will be audible noises from the suspension assembly, possibly springs banging against the housing. A very loud, unusual noise always indicates abnormal operation and damage could result.

The bearings on the $\mathrm{V}-5$ Vibrator eccentrics are spherical rollers, their loading is radial and equal each to $1 / 8$ of the dynamic force, created by the rotating eccentrics. The statistical life of these bearings is shown on Fig. 16, Page 20.
II. OPERATING INSTRUCTIONS
E. CHARACTERISTICS - Continued

FIG. 15

FIG. 16
III. MAINTENANCE AND ADJUSTMENTS

## A. GENERAL

The V-5 Vibrator and HP-105 Hydraulic Power Pack should be inspected regularly to help keep it in good operating condition. The time interval between necessary adjustments and repairs depends primarily on how much and how hard the machine has been used. Repair or replace broken or damaged parts as soon as they are discovered. Periodic cleaning and repainting will help keep all parts in better working order and prolong the machine's life.

The diesel-driven, HP-105 hydraulic power pack has been designed to minimize field downtime by making most components replaceable as units. Field maintenance will generally be limited to the regular preventative maintenance procedures detailed below.

The vibrator is run-in and checked thoroughly at the factory for leaks and possible malfunctions. The vibrator bearing-gear enclosure is completely sealed with a closed, forced lubrication system requiring a minimum of checking.

The removal of the movable jaw is done by pushing out the $3 / 4^{\prime \prime}$ rollpin, either up or down. The single, vertical rollpin captivates the movable jaw. The fixed jaw is held tight against the housing with two 1 " bolts. Operating the V-5 on piling without the jaw shields could result in jaw damage if the vibrator is dropped onto the pile.

Frequent inspection of the vibrator is encouraged. Removal of the side cover opens to view the motor and pump couplings, the lube piping, the end of the gears and an end view of the bearings. Always assure that the couplings are fixed securely and the gear lineup is correct. Removal of the cover plate on the heavy bearing cover will expose all bearings at that end. If it is suspected that the eccentrics are locked, remove the $1^{\prime \prime}$ socket head pipe plug above the fill spout on the bearing cover plate, insert the hex wrench into the socket head pipe plug in the end of the drive shaft and try to rotate by turning clockwise.Ref. Fig. 19.

The hydraulic motor on the vibrator will have a normal drain when operating at pressures $1000-2000$ psi of 6-8 GPM. Motor repair may be required if drains exceed 8 GPM.

## B. DAILY CHECK LIST

CHECK THE ENTIRE UNIT PRIOR TO AND DURING START-UP AT EACH SHIFT.

1. Prior to starting the engine at each shift, check as follows:
a. Make all daily lubrication and preventative maintenance checks indicated in the engine manufacturer's operating and maintenance manuals.
b. Check the hydraulic oil level before starting the engine. Recheck this level after filling the lines to be sure it remains in the safe operating range. DO NOT operate the unit with the hydraulic oil level below $3 / 4$.
c. Visually check all hoses for signs of damage or cuts that might cause hose failure during operation. Be sure all connections are tight, especially the quick disconnects.
d. Look for any damage to the unit in general that might cause it to fail when put into operation.
e. Check tightness of screws on hydraulic motor, lube pump, spring shields, etc. Look for cracks at stressed areas.
f. Check spacing under lifting head. Should be fairly equal distance. Unequal spacing could be a sign one of the springs or spring containers is broken.
g. Be sure there is fuel in tank.
h. Be sure there is cooling fluid in radiator.
III. MAINTENANCE AND ADJUSTMENT
B. DAILY CHECK LIST - Continued
2. After start-up and $V-5$ is vibrating, check as follows:
a. Inspect the hydraulic lines for leaks.
b. Inspect the oil seal areas in the pump drive and control valves for leaks.
c. Allow hydraulic oil temperature to come up slightly above the oil pour temperature preferably to $30^{\circ} \mathrm{F}$. before starting vibrator.
d. Before attaching to pile, open and close clamp jaws to verify fast and positive action.
e. Be sure there are no kinks in the lines and that they hang uniformly.
f. Once the vibrator has been started, be sure lube oil is pumping. Ref. Section III. C.3.
g. Always maintain close check on the lifting cable to assure no fraying has occurred.
h. Oil the lifting shafts and grease the guide bushings generously. Check for overheated bearing housings.
i. Be sure clamp jaws open and close.
j. Maximum engine speed is 2200 RPM.

## III. MAINTENANCE AND ADJUSTMENTS

## C. LUBRICATION

1. Diesel Engine - should read:

An SAE-30 ofl is recommended for year-round use. The use of lower viscosity oils or multigrade products will usually result in less than normal engine life. Recommended oils for crankcase:

| Exxon | HDX Plus 30 |
| :--- | :--- |
| Gulf | Gulflube XHD-30 |
| Mobil | Delvac 1230 |
| Shell | Rotella T-30 |
| Texas | Ursa Extra Duty 30 |
| Standard | Facto 30 |

RECOMMENDED FUEL FOR DIESEL ENGINE:

No. 2 Diesel Fuel $0 i 1$
The diesel engine maximum governed speed should be set at 2200 RPM.

The air cleaner must be serviced frequently depending on the dust conditions. Replace the oil in the air cleaner when it becomes dirty using the same kind of oil that is used in the crankcase. Consult the engine manufacturer's manual for complete information concerning the air cleaner.

The cooling system capacity for the 4-53 Diesel Engine is 25 quarts. In winter months, use about $40 / 60$ solution of anti-freeze and water or about 10 quarts anti-freeze.

## III. MAINTENANCE AND ADJUSTMENTS

C. LUBRICATION - Continued
2. Hydraulic System

The hydraulic system in the HP-105 power unit requires highly dependable fluids to provide maximum efficiency and continuity of operation. The fluid must operate over wide temperature ranges, keep the system free from rust, separate quickly from water encountered from either contamination or condensation, and protect all parts from wear over extended periods of service. The fluid must have extra anti-wear characteristics. The hydraulic fluid recommended is:

Texaco Rando HDA or equivalent.
This is a SAE-10 oil which meets all the requirements above. Fill the reservoir to "full" capacity and check level daily, not to operate below $3 / 4$ capacity. Drain and flush the entire system at least once a year, depending on use of equipment. It may be necessary to change it more frequently depending on the operating conditions. The hydraulic tank capacity is 80 gallons.

WARNING: WHEN REPLACING OR ADDING OIL, BE EXTREMELY CAREFUL TO KEEP FOREIGN MATTER FROM ENTERING THE OIL AND THE SYSTEM. DIRT, DUST, ETC., WILL HARM OR INTERFERE WITH THE OPERATION OF THE PUMPS AND VALVES.

Mixing different manufacturers' hydraulic oils can be done if they are miscible, (same base and additives). Check with oil suppliers or factory.
III. MAINTENANCE AND ADJUSTMENTS
C. LUBRICATION - Continued
2. Hydraulic System - Continued

The hydraulic oil filter, Reference Fig. 5, and Fig. 6, Page 9, is to be inspected frequently, especially after additions of hydraulic fluid, change of hydraulic lines, disconnection of hoses or when operating conditions are dusty. Recommended frequency of filter change is every month of operation. The filter element is a throw away Schroeder K25 (25 Micron).

The hydraulic motor on the vibrator requires a drain line to relieve case pressure inside the motor. The motor drain line back-to-tank has a "blow off" safety valve located in the line on the vibrator, Ref. Fig. 17. The "blow off" relief valve setting recommended is $40-50 \mathrm{psi}$ to protect the motor seals and interior components. If this pressure is surpassed by a kink in the line or incorrect connection at the power unit tank or any resistance of flow to tank oil will spill at the valve. The clamp cylinder has two hose lines leading from the cylinder to the power unit valve. The clamp cylinder is powered in both directions, operating the jaws to open and close.

## III. MAINTENANCE AND ADJUSTMENTS

C. LUBRICATION - Continued
3. Vibrator

Vibrator lubrication is basically automatic and an occasional check of flow by removing one of the two top pipe plugs in the bearing cover is all that should be required. See Fig. 18. The gear-bearing-eccentric housing is sealed and the oil level should not change.

FIG. 18

The lube oil supplied by the factory is Shell Tellus 933, SAE 30. The basic requirement for this oil is good lubricating qualities, that is: an EP (extreme pressure), a high viscosity index above (100) and a relatively low pour point.

## III. MAINTENANCE AND ADJUSTMENTS

## C. LUBRICATION - Continued

## 3. Vibrator - Continued

A check on the lube oil level is made by removing the lower pipe plug on the bearing end cover opposite motor housing. The oil level should be to the bottom of this pipe plug hole when the vibrator is level. Ref. Fig. 19.

If the level of oil is above this pipe plug opening or lube oil volume increasing, this will indicate that the hydraulic motor is leaking hydraulic fluid through the motor drive shaft seal. The seal leakage must be corrected immediately. The mixture of hydraulic oil and lube oil is not a lube problem but the increased level will add load to the rotating eccentrics and cause excessive foaming. The side cover, closest to the hydraulic motor housing, can be removed and an inspection of the oil and coupling connectors to the lube pump and eccentrics can be made.

## C. LUBRICATION - Continued

3. Vibrator - Continued

The clamping assembly moving jaw slide is not lubricated. If desired, a coating of "Moly-Kote" could be applied, but do not use oils or grease since they will pick up dirt and grit. The suspension assembly has six grease fittings, one on each bushing. These bushings are to be greased regularly to minimize bushing wear.

The lube filter assembly is shown on Fig. 20 below. This is a suction, low pressure filter, a cleanable type, with a monel 74 micron element. The filter element is a Marvel No. 1120. The indicator ring at the bottom will return its original position when stopped but an 0-ring will indicate the last position. If the 0-ring is in the red, the filter must be cleaned. Recommended cleaning is every week of operation. After cieaning the filter element, be sure to return the 0 -ring back to the green area.

IV. HYDRAULIC SYSTEM
A. CIRCUITRY

The repetitive functions to be performed hydraulically, for the operation of the V-5 Vibrator is first to be able to clamp on to a pile, vibrate the pile, stop vibrating, and unclamp from the pile. One basic, open loop, hydraulic circuit has been used, with a single pump performing both clamping and vibrating operations. The principle of using one pump is dependent on a clamping hydraulic cylinder that has an integrated holding pressure check valve, meaning once the pressure has been applied and immediately removed, the pressure will be locked in the cylinder. The tandem circuit design valve, with two plungers, is of the open center type. This valve is not required to hold a load in neutral. The valve consists of an inlet section with an adjustable pressure relief, two working sections, the plunger nearest to the inlet takes priority over the oil supply, and an outlet section. The plunger nearest the inlet is the clamp valve and the other is the main drive or vibrate valve.

Following the hydraulic circuit, Fig. 21, Page 31, the oil from the pump goes directly to tank through each spool when each plunger is in the vertical position. The plunger nearest the inlet operates the clamp circuit. A quick and full plunger movement operates the clamp in a fraction of a second with a spring return neutral position. The second plunger operates the vibrate circuit and is two position only, forward and neutral. The single position is necessary to assure the vibrator motors rotate in one direction because the lube pump only pumps in one direction. It is necessary to move the plunger back to neutral position to stop since the plunger has detents held in all positions.

FIG. 21

IV. HYDRAULIC SYSTEM - Continued

## A. CIRCUITRY - Continued

All oil passing through the valve back to tank from the cylinder or motor line in the vibrator is directed through an oil heat exchanger located in front of the water radiator. Before the oil enters the tank, it is filtered through a 10 micron reclaimable filter. The hydraulic oil sucked up from the reservoir must pass through a magnetic separator which separates magnetic particles as small as 1 micron in size from the fluid. Non-ferrous particles adhering to the magnetic particles through the viscous action of the fluid are also removed.

The pressure gage is protected by a snubber of flow control valve to protect the sensitive valve needle. The temperature gage measures reservoir hydraulic fluid temperature, which should not exceed $170^{\circ}$ F. during operation. Hydraulic oil temperature rises may approach $170^{\circ} \mathrm{F}$. when operating at maximum vibrator load. Running the hydraulic power unit without load will lower the temperature.

## VI. PARTS IDENTIFICATION

The component parts of each assembly drawing are identified by a balloon with a number inserted called an item number. When ordering a component part, use only the seven digit number to the right of the vertical line through the part number block.

LOCATION OF SERIAL MUNBERS

The location of the Serial Number on our equipment is as follows:

Steam/Air Pile Hammers - Located on the left front on each part (top head, cylinder, etc.).

Steam/Air Extractors - Located on the left side front and each sidestrap.

Diesel Pile Hammers - Located on the instruction plate above the travel plug on the front of the hammer.

Vibratory - Located on the center post of the control side of the power pack. Located on the left side or motor side of the exciter housing.

KA-MO Units - Located on the front of the roller base and the top of the motor housing.

# SALES \& SERVICE BULLETIN 

## SYSTEM SERIAL NUMBERS

Up until the present, MKT has been selling vibratory and earth boring systems. As such, when the sale was effected, both the power packs and the exciter or boring unit had been assigned the same serial number.

Now it has become obvious that these systems will, on occasion, be sold as separate items. Hence:
(A) Major system items supplied separate from a matched system will be assigned a sequential serial number.
(B) Major system items supplied in a matched system will have a suffix on the serial number identifying the component.

1. Power Packs, Suffix P.
2. Vibratory Exciters, Suffix E.
3. Earth Augers, Suffix A.

## EXAMPLE:

A V-14 Vibratory System will have a Serial Number on the Power Pack marked 741101P and the Exciter will be marked 741101E.

V-5 VIBRATORY HAMMER POWERED BY THE HP- 210 ( $\mathrm{V}-14 \mathrm{P} / \mathrm{P}$ )

The V-14 Power Pack can be used to power the V-5 Vibratory Hammer. The clamp circuit and drain line can be connected directly between the power pack and the vibrator. The motor line flow and pressure must each be lowered to safely operate the V-5 Vibrator. The maximum pressure over relief for the motor line must be set at 2500 psi. The maximum flow must be set at about 54 gpm for a free hanging frequency of $1450-1500 \mathrm{cpm}$. cpm . The actual. flow to the vibrator motor is not easily measured but by the manipulation of the fast and slow button on the control pendent, the measured frequency of $1450-1500 \mathrm{cpm}$ can be set.

When setting the motor drive pressure to a maximum of 2500 psi , over relief, check the actuator rotation when depressing the slow button. The actuator will stop when one of the switch rollers dips off the cam high path. Carefully hold out this roller to permit the acuator to continue rotating the cam a little further with the slow button depressed (Note, the vertical rod on the pump will rise). Connect the vibrator to the motor lines of the power pack and check the vibrator frequency while free hanging.

REPLACING THE GASKET BETWEEN THE V-5 BEARING HOUSING AND EXCITER HOUSING

Four eccentric supported bearings are tightly fitted into the V-5 Bearing Housing and one jack shaft bearing cartridge is slip fitted into this same bearing housing. A gasketed plate covers the eccentric bearings and retains the jack shaft bearing cartridge. Reference the V-5 Manual, Fig. 24, Page 36. The eccentric bearings are a slip fit on the eccentrics and the jack shaft bearings are tightly fitted onto the jack shaft. A. 030 Gasket, 34050040 , is affixed to the Bearing Housing, 44050004 with Permatex.

To remove the large Bearing Housing, 44050004, first remove the Bearing Cover, 34050093 , and try sliding out the Jack Shaft Bearing Cartridge, 34050092. If the cartridge will not pull out, remove the entire bearing housing and the cartridge may come with it. In doing so, the Jack Shaft, 34050010, Bearing, 09140001, may come apart by the scparating force between the outer and inner race. This will not damage the bearing and it can be reassembled.

Replace the Bearing Housing Gasket, 34050040 , and assemble by applying Permatex to the Bearing Housing, 44050004. Assemble the bearing housing by lowering and carefully fitting the bearing inner races on the eccentric shafts. Light tapping of the inner race may be necessary to help guide the bearings. Do not assemble the Jack Shaft Bearing Cartridge, 34050092, at this time. After the bearing housing is fully seated and bolted, guide in the bearing cartridge which will slip fit into the housing and over the bearing outer race. Reassemble the Bearing Cover, 34050093, replacing its Gasket, 34050095 , only if damaged. The Bearing Cover Gasket, 34050095 , is affixed to the bearing cover with Permatex.

If a jack shaft bearing has to be replaced, its removal from the jack shaft will be difficult because of an interference fit of .001 to .002 . Application of heat and a puller may be used. Replacement and assembly of a Jack Shaft Bearing, 09140058, to the jack shaft is donc by heating the bearing in oil at a temperature of about $250^{\circ} \mathrm{F}$., and positioning the bearing tight against the jack shaft shoulder.

## SALES \& SERVICE BULLETIN

## V-5 LUBE FILTER ELEMENT MOVEMENT

The vertically mounted filter assembly has a cleanable type monel element that fits into the cast housing with a small amount of end play. The high G loading caused by the vibrator could cause the filter, thrusted vertically, to crush itself. We have added a washer-spacer that prevents the element from moving. Some earlier V-5 units may not have had this spacer added. The spacer is a $11 / 8^{\prime \prime}$ flat washer with $11 / 4^{\prime \prime}$ I.D., $23 / 4^{\prime \prime} 0 . D$ and . $19^{\prime \prime}-.22^{\prime \prime}$ thickness.
